Class 12

Emmanuel Robles

Import the data

We need two things for this analysis: - countdata (counts for every transcript/gene in each experiment) - coldata (metadata that describes the experimental setup)

```
countData <- read.csv("airway_scaledcounts.csv", row.names=1)
head(countData)</pre>
```

	SRR1039508	SRR1039509	SRR1039512	SRR1039513	SRR1039516
ENSG00000000003	723	486	904	445	1170
ENSG0000000005	0	0	0	0	0
ENSG00000000419	467	523	616	371	582
ENSG00000000457	347	258	364	237	318
ENSG00000000460	96	81	73	66	118

	SRR1039517	SRR1039520	SRR1039521		
ENSG00000000003	1097	806	604		
ENSG00000000005	0	0	0		
ENSG00000000419	781	417	509		
ENSG00000000457	447	330	324		
ENSG00000000460	94	102	74		
ENSG00000000938	0	0	0		

```
metadata <- read.csv("airway_metadata.csv")
head(metadata)</pre>
```

```
id dex celltype geo_id
1 SRR1039508 control N61311 GSM1275862
2 SRR1039509 treated N61311 GSM1275863
```

```
3 SRR1039512 control N052611 GSM1275866
4 SRR1039513 treated N052611 GSM1275867
5 SRR1039516 control
                     N080611 GSM1275870
6 SRR1039517 treated N080611 GSM1275871
```

Q1. How many genes are in this dataset?

```
nrow(countData)
```

[1] 38694

Q2. How many "control" cell lines do we have?

```
table(metadata$dex)
```

```
control treated
      4
```

Another method

```
sum(metadata$dex == "control")
```

[1] 4

- Step 1 Calculate the mean of the control sample Calculate the mean of the trated samples
- (a) We need to find which columns in countData are "control" samples.
- Look in the metadata (a.k.a. colData), \$dex column

```
control.ind <- metadata$dex == "control"</pre>
```

(b) Extract all the control columns from countData and call it control.counts

```
control.counts <- countData[ ,control.ind]</pre>
```

(c) Calculate the mean values across the rows of control and calculate the mean count values

```
control.means <- rowMeans(control.counts)
head(control.means)</pre>
```

```
ENSG00000000003 ENSG0000000005 ENSG000000000419 ENSG000000000457 ENSG000000000460
900.75 0.00 520.50 339.75 97.25
ENSG00000000938
0.75
```

• Step 2 Calculate the mean of the treated samples...

```
treated.ind <- metadata$dex == "treated"
treated.counts <- countData[ ,treated.ind]
treated.means <- rowMeans(treated.counts)
head(treated.means)</pre>
```

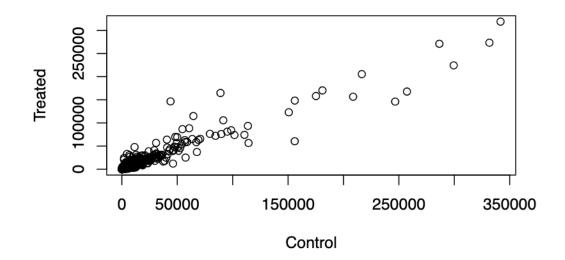

```
ENSG00000000003 ENSG0000000005 ENSG00000000419 ENSG00000000457 ENSG000000000460 658.00 0.00 546.00 316.50 78.75 ENSG00000000938 0.00
```

We now have control and treated mean count values, For ease of keeping I will combine these vectors into a new data.frame meancounts.

```
meancounts <- data.frame(control.means, treated.means)
head(meancounts)</pre>
```

	control.means	treated.means
ENSG0000000003	900.75	658.00
ENSG00000000005	0.00	0.00
ENSG00000000419	520.50	546.00
ENSG00000000457	339.75	316.50
ENSG00000000460	97.25	78.75
ENSG00000000938	0.75	0.00

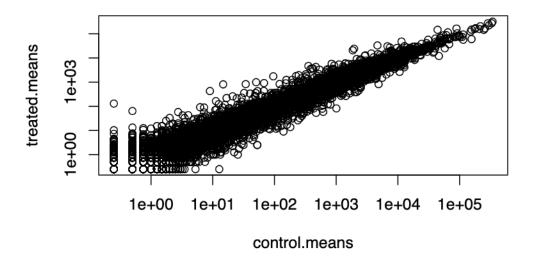

```
plot(meancounts[,1],meancounts[,2], xlab="Control", ylab="Treated")
```

plot(meancounts, log="xy")

Warning in xy.coords(x, y, xlabel, ylabel, log): 15032 x values <= 0 omitted from logarithmic plot

Warning in xy.coords(x, y, xlabel, ylabel, log): 15281 y values <= 0 omitted from logarithmic plot

We use log transforms for skewed data such as this ans because we really care most about relative changes in magnitude.

```
log2(20/20)

[1] 0

If I have half the amount I will have log2 fold-change of -1
log2(10/20)
```

[1] -1

If I have double the amount (20 compared to 10), change of +1

```
log2(20/10)
```

[1] 1

```
meancounts$log2fc <- log2(meancounts$treated.means / meancounts$control.means)
   Q. How many genes are upregulated at the common threshold of +2 log2FC values?
   sum(meancounts$log2fc >= 2, na.rm=TRUE)

[1] 1910

  dds <- DESeqDataSetFromMatrix(countData = countData,</pre>
                                 colData = metadata,
                                 design = ~dex)
converting counts to integer mode
Warning in DESeqDataSet(se, design = design, ignoreRank): some variables in
design formula are characters, converting to factors
To run the analysis I can now use the main DESeq2 function called DESeq() with ads as
input.
  dds <- DESeq(dds)
estimating size factors
estimating dispersions
gene-wise dispersion estimates
mean-dispersion relationship
```

final dispersion estimates

fitting model and testing

To get the results back from this object we can use the results() function from the package.

```
res <- results(dds)
head(res)</pre>
```

ENSG00000000457	0.961694				
ENSG00000000460	0.815849				

Let's make a final (for today) plot of log2 fold-change vs the adjusted p-value.

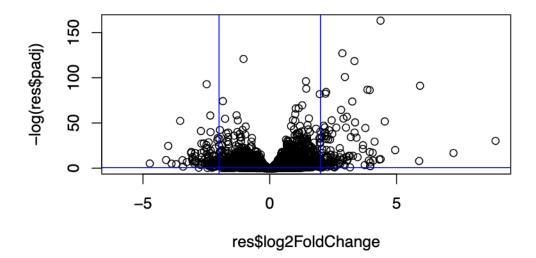

```
plot(res$log2FoldChange, res$padj)
```

NA

It is the low p-values that we care about and these are lost in to our skewed plot above.

```
plot(res$log2FoldChange, -log(res$padj))
abline(v=c(+2, -2), col="blue")
abline(h= -log(0.5), col="blue")
```

Finally we can make a color vector to use in the plot to highlight the genes we care about.

```
mycols <- rep("grey", nrow(res))
mycols[abs(res$log2FoldChange) >= 2] <- "red"
mycols[res$padj] <- "grey"
#mycols

plot(res$log2FoldChange, -log(res$padj), col= mycols)
abline(v=c(+2, -2), col="blue")
abline(h= -log(0.5), col="blue")</pre>
```
